APPLICATION ELEMENTS

1. ☐ Fee Transmittal Form (PTO/SB/56)
(Submit an original, and a duplicate for fee processing)
2. ☒ Specification and Claims (amended, if appropriate)
3. ☒ Drawing(s) (proposed amendments, if appropriate)
4. ☐ Reissue Oath/Declaration (original or copy)
(37 CFR 1.175) (PTO/SB/51 or 52)
5. ☒ Original U.S. Patent
☐ Offer to Surrender Original Patent (37 CFR 1.178)
(PTO/SB/53 or PTO/SB/54)
or ☐ Ribbonded Original Patent Grant
☐ Affidavit/Declaration of Loss (PTO/SB/55)
6. Original U.S. Patent currently assigned?
☒ Yes ☐ No
(If Yes, check applicable box(es))
☐ Written Consent of all Assignees (PTO/SB/53 or 54)
☐ 37 CFR 3.73(b) Statement ☐ Power of Attorney

ACCOMPANYING APPLICATION PARTS

7. ☒ Transfer Drawings from Patent File
8. ☐ Foreign Priority Claim (35 USC 119)
9. ☐ Information Disclosure Statement (IDS)/PTO-1449 ☐ Copies of IDS Citations
10. ☐ English Translation of Reissue Oath/Declaration (if applicable)
11. ☐ Small Entity Statement(s) ☐ Statement filed in prior application Status still proper and desired
12. ☐ Preliminary Amendment
13. ☒ Return Receipt Postcard (MPEP 503)
(Should be specifically itemized)
14. ☒ Other: Copy original patent

LETTER ACCOMPANYING REISSUE APPLICATION

Sir:

Pursuant to the practice under 37 C.F.R. § 1.53 and
M.P.E.P. §§ 601.01, 1410, enclosed herewith for filing are
the following papers constituting an application for reissue
of United States Letters Patent No. 5,759,080, issued June 2,
1998, to SEISHIRO YOSHIOKA ET AL. for DISPLAY DEVICE WITH
ELECTRON-EMITTING DEVICE WITH ELECTRON-EMITTING REGION
INSULATED FROM ELECTRODES.

1. Mounted soft copy of the specification and new claims.

2. A copy of the patent drawings.

3. A soft copy of the printed original patent.

4. A check in the amount of \$4,076.00 computed as follows:

Basic Filing Fee \$ 690.00

Independent claims in excess of the number of independent claims in the original patent

(23 X \$78) \$1,794.00

Claims in excess of twenty and also in excess of the number of claims in the original patent

(73 x \$18) \$1,314.00

Fee for multiple dependent

claims \$ 260.00

Total: \$4,058.00

This reissue application is filed on behalf of the inventors, Seishiro Yoshioka, Ichiro Nomura, Hidetoshi Suzuki, Toshihiko Takeda, Tetsuya Kaneko, Yoshikazu Banno, and Kojiro Yokono, all citizens of Japan, and each having a post office address of c/o Canon Kabushiki Kaisha, 30-2, Shimomaruko 3-chome, Ohta-ku, Tokyo, Japan.

Applicants hereby claim priority and preserve all rights to which they are entitled under 35 U.S.C. § 119 based on the following Japanese patent applications:

<u>Appln. No.</u>	<u>Filed</u>
62-174837	July 15, 1987

63-102488	April 27, 1988
63-154516	June 21, 1988

Applicants hereby offer to surrender the Letters Patent No. 5,759,080.

Pursuant to 37 C.F.R. § 1.174, please transfer the drawings from the patent file to the subject reissue application and, if necessary, prepare mounted copies of the original drawings, charging the cost of the mounted copies to Deposit Account No. 06-1205.

U.S. Patent No. 5,759,080 is assigned of record to Canon Kabushiki Kaisha, Tokyo, Japan. The assignee hereby consents to this reissue.

The undersigned attorney has been authorized to file the subject reissue application on behalf of the inventors and the assignee.

The Commissioner is hereby authorized to charge any additional fees that may be required under 37 C.F.R. § 1.16 or § 1.17, and to credit any overpayment, to Deposit Account No. 06-1205.

Applicants' undersigned attorney may be reached in our New York office by telephone at (212) 218-2100. All correspondence should continue to be directed to our address given below.

Respectfully submitted,

Attorney for Applicants

RELATED APPLICATION

This application is a reissue of U.S. Patent No. 5,759,080, which issued from application Ser. No. 08/479,000, which is a division of application Ser. No. 08/396,066 filed Feb. 28, 1995, now abandoned which is a continuation of application Ser. No. 08/191,065 filed Feb. 3, 1994, now abandoned, which is a continuation of application Ser. No. 07/705,720 filed May 24, 1991, now abandoned which is a continuation-in-part of application Ser. No. 07/218,203 filed Jul. 13, 1988 and issued as U.S. Pat. No. 5,066,883 on Nov. 19, 1991.

BACKGROUND OF THE INVENTION

1. Field of the Invention

The present invention relates to an electron-emitting device, and a method of preparing it.

2. Related Background Art

Hitherto known as a device achievable of emission of electrons with use of a simple structure is the cold cathode device published by M. I. Elinson et al. (Radio Eng. Electron. Phys., Vol. 10, pp. 1290-1296, 1965).

This utilizes the phenomenon in which electron emission is caused by flowing an electric current to a thin film formed with a small area on a substrate and in parallel to the surface of the film, and is generally called a surface conduction electron-emitting device.

This surface conduction electron-emitting device that has been reported includes those employing a $\text{SnO}_2(\text{Sb})$ thin film developed by Elinson et al. named in the above, those employing an Au thin film (G. Dittmer, "Thin Solid Films", Vol. 9, p.317, 1972), those employing an ITO thin film (M. Hartwell and C. G. Fonstad, "IEEE Trans. ED Conf.", p.519, 1975), and those employing a carbon thin film [[Hisashi Araki, et al. "SHINKU" (Vacuum), Vol. 26, No. 1, p 22, 1983].] (Hisashi Araki, et al. "SHINKU" (Vacuum), Vol. 26, No. 1, p.22, 1983).

Typical device constitution of these surface conduction electron-emitting devices is shown in FIG. 38. In FIG. 38, the numerals 19 and 20 denote electrodes for attaining electrical connection; 21, a thin film formed using an electron-emitting material; 23, a substrate; and 22, an electron-emitting region.

In these surface conduction electron-emitting devices, it has been hitherto practiced to previously form the electron-emitting region by an energizing heat treatment, called "forming", before effecting the electron emission. More specifically, a voltage is applied between the above electrode 19 and electrode 20 to energize the thin film 21 to bring the thin film 21 to be locally destroyed, deformed or denatured owing to the Joule heat thereby generated, thus forming the electron-emitting region 22 kept in a state of electrically high resistance to obtain an electron-emitting function.

What is meant by the above state of electrically high resistance is a discontinuous state of a film partly having cracks of 0.5 μm to 5 μm on the thin film 21 and having the so-called island structure inside the cracks. What is meant by the island structure is the structure of a film in which fine particles generally having a diameter of several ten angstroms to several micrometers are present on the substrate, and the respective fine particles are spatially discontinuous and electrically continuous.

Hitherto, in the surface conduction electron-emitting devices, a voltage is applied to the above high-resistance

09587249-060200

discontinuous film by the electrodes 19 and 20 to flow an electric current to the surface of the device, so that the electrons are emitted from the above fine particles.

However, the forming according to the conventional energizing heat treatment as mentioned above has involved the problems as follows:

- (1) In carrying out the energizing heating, it sometimes occurs that the thin film is peeled because of the difference in coefficient of thermal expansion between the substrate and the thin film. This provides limitations in upper limit of heating temperature, materials for the substrate, and combination by selection of materials for the thin film.
- (2) In carrying out the energizing heating, the substrate also is locally heated, therefore sometimes resulting in occurrence of fatal cracking therein.
- (3) Degree of the changes of a film owing to the energizing heating, as exemplified by the degree of local destruction, deformation or denaturing, tends to become irregular among a plurality of devices formed in the same substrate, and also the site at which changes may occur tends to be not fixed.
- For this reason, when functioning as an electron emitting device, irregularity in the shape of beams of emitted electrons has been seen for each device.
- (4) A relatively large electric power is required until the forming is completed. For this reason, an electric source of large capacity is required when a number of devices are formed on the same substrate and the forming is carried out simultaneously.
- (5) A relatively long period of time is required for conventional forming processes that start with the energizing heating and end with cooling. For this reason, an excessively long time is required for carrying out the forming of a number of devices.

Because of the problems as set out above, the surface conduction electron-emitting devices have not been positively applied in industrial fields, notwithstanding their advantages that the device has simple construction.

SUMMARY OF THE INVENTION

The present invention was made to eliminate the disadvantages in the prior art as discussed above, and an object thereof is to provide an electron-emitting device that can have, without applying the treatment called forming, a quality more than equal to that of electron-emitting devices obtained by the forming, and has a novel structure suffering less irregularity of characteristics, and a method for preparing it.

More specifically, the present invention firstly provides a means for preparing the device by controlling the above-mentioned shape and width of cracks without use of the forming means, and with ease, and provides an electron-emitting device with regular characteristics, prepared by the method using the means.

It secondly provides a means for making uniform the structure and size corresponding to the island structure in the cracks mentioned above, and provides an electron-emitting device having regular characteristics by using the means.

A further object of the present invention is to provide an electron-emitting device capable of controlling the above characteristics and also capable of better controlling the position of the electron-emitting region, and a method for preparing such a device.

A still further object of the present invention is to provide an electric current emitting device that not only can solve the problems previously mentioned, but also can make lower the

09587249 060300

According to an aspect of the present invention, there is provided an electron-emitting device comprising a laminate comprising an insulating layer held between a pair of electrodes opposing each other, wherein an electron-emitting region insulated from said electrodes is formed at a side end surface of the insulating layer formed at the part at which the electrodes oppose each other, and electrons are emitted from said electron-emitting region by applying a voltage between said electrodes.

According to a further aspect of the present invention, there is provided an electron-emitting device comprising the device structure that a semiconductor layer is formed between opposing electrodes, and fine particles are arranged inside the layer, or on the layer, of said semiconductor layer in a dispersed state.

A further object of the present invention is to provide a display device comprising an electron-emitting device in which electron-emitting material comprising the electron-emitting region are in a dispersant state.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 2 is a cross-section illustrating another embodiment of a vertical type electron-emitting device of the present invention.

FIG. 4 is a cross-section illustrating an embodiment of a vertical type electron-emitting device of the present invention.

FIGS. 6a and 6b illustrate examples for a method of preparing an embodiment of an electron-emitting device of the present invention.

FIG. 7 illustrates a further step in a method of preparing an embodiment of an electron-emitting device of the present invention.

FIG. 8 is a perspective view illustrating an electron-emitting device of the present invention having an insulating layer comprising fine particles arranged in a dispersed state;

FIG. 9 and FIG. 10 are cross sections along line A in FIG. 8;

FIGS. 11(A) to 11(E) are cross-sections illustrating the preparation steps of an electron-emitting device of the present invention.

FIG. 12 illustrates a preparation step of an electron-emitting device of the present invention.

FIGS. 13(a) and 13(b) illustrate preparation steps of another embodiment of an electron-emitting device of the present invention.

FIGS. 14(A) to 14(E) are cross-sections illustrating each of the preparation steps of another embodiment of an electron-emitting device of the present invention.

FIGS. 15(a) and 15(b) illustrate preparation steps of another embodiment of an electron-emitting device of the present invention.

FIGS. 16(a) and 16(b) illustrate preparation steps of another embodiment of an electron-emitting device of the present invention.

FIGS. 17 and 18 diagnostically illustrate an electron-emitting device of the present invention having a semiconductor layer comprising fine particles arranged in a disposed state.

FIGS. 19(A) to 19(C) are cross-sections illustrating an electron-emitting device of the present invention for each preparation step.

FIG. 20 diagrammatically illustrates an embodiment of an electron-emitting device of the present invention having a semiconductor layer comprising fine particles arranged in a dispersible state.

FIGS. 21 and 22 diagrammatically illustrate other embodiments of an electron-emitting device of the present invention.

FIGS. 23(A) to 23(D) illustrate the step in the preparation of an embodiment of an electron-emitting device of the present invention.

FIGS. 24 and 25 are cross-sections illustrating embodiments of an electron-emitting device of the present invention.

FIGS. 26(A) to 26(E) are cross-sections illustrating the preparation steps of an embodiment of an electron-emitting device of the present invention.

FIG. 27 illustrates another embodiment of an electron-emitting device of the present invention.

FIGS. 28(a) to 28(c), FIGS. 29(a) to 29(c), and FIGS. 30(a) to 30(d) illustrate preparation steps in other embodiments of an electron-emitting device of the present invention.

FIG. 31 illustrates another embodiment of an electron-emitting device of the present invention.

FIGS. 32(a) and 32(b); FIGS. 33(a) to 33(d) and FIGS. 34(a) to 34(d) illustrate the preparation steps in other embodiments of an electron-emitting device of the present invention.

FIGS. 35 and 36 diagrammatically illustrate an electron-emitting device according to other embodiments of specific structures of the present invention.

FIGS. 37(a) and 37(b) illustrate an electron-emitting device comprising two kinds of fine particles arranged in a dispersed state; and

FIG. 38 is a view illustrating a conventional electron-emitting device

FIG. 39A is partially cutaway perspective view illustrating the structure of a display panel.

FIG. 39B illustrates an example of the display device having electrodes 1 and 2 juxtaposed on a surface of a substrate.

FIG. 39C illustrates an example of the display device in which electrodes 1 and 2 are laminated on a substrate.

FIG. 39D illustrates an upper view of the laminate in FIG. 39A formed of three layers.

DETAILED DESCRIPTION OF PREFERRED EMBODIMENTS

More specifically, the present invention is an electron-emitting device comprising a laminate comprising an insulating layer disposed between a pair of opposing electrodes, wherein an electron-emitting region insulated from the electrodes is provided at a side end surface of the insulating layer formed at the part at which the electrodes oppose each other, and electrons are emitted from the electron-emitting region by applying voltage between the electrodes.

FIG. 1 diagrammatically illustrates a first embodiment of the electron-emitting device of the present invention. In the figure, the numerals 1 and 2 denote electrodes for obtaining electrical connection; 3, an electron-emitting region; 4, a substrate; and 5, an insulating layer.

In FIG. 1, the electron-emitting device of the present invention comprises a laminate comprising the insulating layer 5 disposed between a pair of the electrodes 1 and 2 opposing each other at their end portions, wherein the electron-emitting region 3 insulated from the electrodes is provided at a side end surface of the insulating layer 5 formed at the opposing part at which the electrodes 1 and 2 oppose each other, and electrons are emitted from the electron-emitting region 3 by applying voltage between the electrodes 1 and 2.

In the above electron-emitting device, the one corresponding to the narrow crack in the prior art can depend on the film thickness of the insulating layer 5. More specifically, as illustrated in FIG. 1, taking the structure that a pair of the electrodes are formed above and beneath the insulating layer with respect to the direction of the lamination in which the insulating layer having the electron-emitting region is laminated to the substrate (hereinafter referred to as "vertical type structure") can make small the thickness of the insulating layer on which the spacing between electrodes depend.

The electron-emitting device having the vertical type structure has a quality more than equal to that of conventional ones without taking the forming means, and can give a more improved electron-emitting device that can make uniform the shape and width of the electron-emitting region.

In FIG. 1, the insulating layer 5 may have a thickness of from several angstroms to several microns, for example, from 10 angstroms to 10 microns, preferably from 10 to 1 μm .

The insulating layer 5 is comprised of SiO_2 , MgO , TiO_2 , Ta_2O_5 , Al_2O_3 or the like, a laminated material of any of these, or a mixture of any of these, which is formed by vacuum deposition or coating. Alternatively, when the electrode 1 is comprised of a metal such as Al and Ta, the insulating layer 5 may comprise an anodic oxidation film anodized by electrolysis.

The substrate 4 is formed with glass, ceramics or the like, and the electrodes 1 and 2 are formed with Au, Ag, Cu, Mo, Cr, Ni, Al, Ta, Pd, W or the like, or an alloy of any of these, or carbon, etc.

The electrodes 1 and 2 may have a thickness of from several hundred angstroms to several μm , preferably from 0.01 to 2 μm in the case of the vertical type. Formation methods include vacuum deposition, photolithography, and printing.

An outline of the method of preparing the electron-emitting device according to the present invention can be specifically described based on FIG. 1 as follows:

The electrode 1 is vapor deposited on the substrate 4, and then subjected to patterning to give a desired shape as exemplified by a stripe. Thereafter, the insulating layer 5 is formed by means of vacuum deposition, coating or the like. Thickness of the insulating layer depends on the dielectric strength depending on materials for the insulating layer, and the threshold voltage at which emission of electrons begins by the voltage applied between the electrodes 1 and 2. Usually, to set the threshold voltage to from 10 to 20 V, this film thickness must be 1 micron or less. After formation of the insulating layer 5, the electrode 2 is formed by conventional vacuum deposition, printing, coating or the like process, and then the electrode 2 and the insulating layer 5 are so subjected to patterning along the pattern of the electrode 1 that they may partly overlap with the electrode 1 in the same pattern (see FIG. 1.). [in] In that occasion, the electron-emitting region 3 may be obtained by disposing an electron-emitting layer 3a between the insulating layers 5a and 5b according to the manner as described later, or may be obtained by disposing electron-emitting bodies 3b at the side face of the insulating layer 5.

Good results can also be exhibited not only by taking the structure in which the electrodes 1 and 2 overlap as shown in FIG. 1, but also by an electron-emitting device comprising the electron-emitting region 3 disposed at a side end surface defined between a pair of electrodes 1 and 2 that oppose at their end portions but have no overlap as shown in FIG. 2.

The electron-emitting region 3 is formed by disposing an electron-emitting layer 3a in the insulating layer 5 comprised of a material readily capable of field emission of electrons, a material readily capable of secondary electron emission, or a material readily capable of emitting electrons by electron bombardment and having strong thermal resistance and corrosion resistance, as exemplified by metals such as W, Ti, Au, Ag, Cu, Cr, Al and Pt, oxides such as SnO_2 , In_2O_3 , BaO and MgO, or carbon or a mixture of any of the above, each having a low work function and high thermal resistance, utilizing vacuum deposition, coating, sputtering deposition, dipping, or the like process.

Alternatively, it may comprise a thin coating comprising superfine particle powder of metals as exemplified by Au, Ag, Cu, Cr and Al, or can be also formed by arranging electron-emitting bodies 3b at the side face of the insulating layer 5 comprising a thin coating of the material as described for the above electron-emitting layer 3a. (Utilizable coating methods include spreading, all sorts of vacuum deposition, and dipping.)

Electrode spacing 6 in FIG. 1 and FIG. 2 somewhat differs, but in approximation may desirably be formed in from several ten angstroms to several μm , preferably from several ten angstroms to 2 μm , and more preferably from 10 angstroms to 1 μm .

An outline of a method for preparing the electron-emitting device illustrated in FIG. 2 will be described below.

An insulating layer 5 is formed on a substrate 4, and a stepped portion is formed by patterning. Thereafter the electrodes 1 and 2 are simultaneously formed into films so

The stepped portion at which the electrode spacing 6 is formed can also be obtained by pattern etching of the substrate 4 itself, without using the insulating layer 5. There is also available a method in which the electrodes 1 and 2 are formed on this stepped portion to obtain an electron-emitting device. (See FIG. 7.)

On the other hand, the electron-emitting device having the structure as shown in FIG. 7 makes it unnecessary for the electrodes to be held by the insulating layer, and makes it possible also to obtain the spacing of the opposing electrodes by utilizing the stepped portion, so that if, for example, the electrode-supporting substrate itself is etched to provide the stepped portion, there is given an electron-emitting device that can be obtained without formation of any insulating layer, making simple its preparation processes.

In FIG. 4 the numerals 1 to 5 denote the same as those

There may be also used a laminate, or a mixture, comprising both these materials. Of course, similar effect can be obtained also when the intermediate layer 8 is provided on the electrode 1 to give a multi-layer electrode. Further, when both the electrodes are made to comprise the multi-layer electrode, suitable materials for the intermediate layer 8 can be selected for each electrode. Also, a laminate comprising an insulating layer 5a, an electron-emitting layer 3a and an insulating layer 5b may be made to comprise a multi-layer laminate constituted of, for example, an insulating layer 5a, an electron-emitting layer 3a, an insulating layer 5b, an electron-emitting layer 3a, an insulating layer 5a, an electron-emitting layer 3a, an insulating layer 5a, and an electron-emitting layer 3a. At least one layer of the multi-layer electrodes, as exemplified by the electrode 2 in FIG. 4, may further preferably be comprised of a material having a high electrical conductivity. This is because the materials for

the intermediate layer 8 are materials having relatively low electrical conductivity as for electrode wiring materials.

An excessively high wiring resistance of a device may cause an increase in the power consumption or a delay in the driving signals, resulting in undesirableness in driving the device. For this reason, the materials having high electrical conductivity are used in the electrode 2 to keep to a low level the wiring resistance of the whole multi-layer electrode. Usable as the materials having high electrical conductivity are Ag, Al, Cu, Cr, Ni, Mo, Ta, W, etc.

In FIG. 4, when the electron-emitting layer 3a comprises the material suffering less sputtering damage or having a low work function, the intermediate layer 8, or the electrode 1 and the intermediate layer 8, may be formed with use of the same materials as in the electron-emitting layer 3a.

The present invention further provides an electron-emitting device having a device structure wherein an insulating layer is formed between electrodes opposing each other, and fine particles are contained in said insulating layer and at the same time arranged in a dispersed state.

Taking the above described device structure of the present invention not only can solve the problems in the prior art previously discussed, but also can provide an electron-emitting device capable of obtaining an emitted electric current of high density by using a low electric power and also capable of controlling the island spacing and island size of the islands previously mentioned. This electron-emitting device will be described below with reference to the drawings.

In FIG. 8, provided on a substrate 4 such as glass and ceramics is an insulating layer 11, and further thereon electrodes 1 and 2 comprised of low-resistance materials for use in voltage application are provided giving minute spacing to form a discontinuous electron-emitting region 10 comprising fine particles 9 dispersed between them. Though not shown in the drawing, a space is taken at an upper area of the electron-emitting region to provide there a lead-out electrode for leading out emitted electrons. Application of voltage between the electrodes 1 and 2 in vacuo (this voltage is assumed as V_p) brings about flow of electricity between the electrodes (I_p) to apply voltage using the lead-out electrode as the anode, so that electrons are emitted from the electron-emitting region in the direction substantially vertical to the paper surface in the drawing. (The electric current for this electron emission is assumed as I_e .)

FIG. 9 and FIG. 10 diagrammatically illustrate cross sections in the A-B direction in FIG. 8. In the present figures, the fine particles on the substrate 4 may preferably have a particle diameter of from several ten angstroms to several μm , and the spacing between respective fine particles may further preferably be formed in the range of from several ten angstroms to several μm .

Materials for the fine particles used in the present invention may cover a very wide range, and almost all of conductive materials including usual metals, semimetals and semiconductors. Particularly suitable are usual cathode materials having properties such as low work function, a high melting point and low vapor pressure, thin film materials capable of forming the surface conduction electron-emitting device by the conventional forming treatment, and materials having a large coefficient of secondary electron emission.

Appropriate materials may be selected from such materials according to purposes and used as the fine particles, so that a desired electron-emitting device can be formed.

Specifically, they may include, for example, borides such as LaB_6 , CeB_6 , YB_4 , and GdB_4 , carbides such as TiC , ZrC ,

HfC, TaC, SiC and WC, nitrides such as TiN, ZrN and HfN, metals such as Nb, Mo, Rh, Hf, Ta, W, Re, Ir, Pt, Ti, Au, Ag, Cu, Cr, Al, Co, Ni, Fe, Pb, Pd, Cs and Ba, metal oxides such as In_2O_3 , SnO_2 and Sb_2O_3 , semiconductors such as Si and Ge, carbon, and AgMg. The present invention is by no means limited by the above materials. Moreover, in the present invention, it may also be practiced to select different materials among the above materials and disperse fine particles of two or more kinds of different materials.

A method for preparing the device illustrated in FIG. 8 will be described below.

FIGS. 11(A) to (E) illustrate cross sections of a device for each preparation step.

- (1) The surface of a substrate 4 comprised of glass or ceramics is degreased and cleaned.
- (2) An insulating layer 11 comprised of low-melting point glass is formed into a film on the surface of the substrate 4 according to liquid-coating baking, printing baking, vacuum deposition, or the like process. Desirable as materials for the low melting point glass are those having a softening point temperature lower than the distortion point temperature of the substrate and at the same time having a coefficient of thermal expansion close to that of the substrate. In general, a lead oxide type low melting glass has a softening point of about 400°C . and also has a coefficient of thermal expansion close to the coefficient of thermal expansion of a soda lime glass substrate generally used. The insulating layer 11 may desirably be formed to have a thickness in the range of from several ten angstroms to several ten μm in approximation.
- (3) On the insulating layer obtained in (2), electrodes 1 and 2 are formed according to vacuum deposition, photolithoetching, lifting-off, printing, or the like process. Usable as electrode materials are the same materials as those described in relation to FIG. 1, i.e. Au, Ag, Cu, Mo, Cr, Ni, Al, Ta, Pd and W, or an alloy of any of these or carbon, etc., and the electrodes 1 and 2 may also suitably have a thickness of from several hundred angstroms to several μm , preferably from 0.01 to 2 μm .

As to the dimension of electrode spacing L, the electrodes may suitably oppose each other with a space of from several hundred angstroms to several ten μm , and spacing width W may suitably be approximately from several μm to several mm. However, they are by no means limited to these dimensions.

- (4) Next, the fine particles 9 are coated on the electrode gap region obtained in (3). A dispersion of fine particles is used in the coating. Fine particles and an additive to promote dispersion of the fine particles are added in an organic solvent comprised of butyl acetate, alcohol or the like, followed by stirring or the like to prepare the dispersion of fine particles. This fine particle dispersion is coated on the surface of a specimen according to dipping, spin coating or the like process, and then calcination is carried out for about 10 minutes at a temperature at which the solvent or the like may be evaporated, for example, at 250°C . Thus the fine particles are arranged on the surface of the insulating layer 11 in the electrode spacing L. Of course, the fine particles 9 are arranged on the whole surface of the specimen, but no difficulty is brought about as there is applied substantially no voltage to the fine particles 9 outside the electrode spacing L when electrons are emitted. This is accordingly not shown in the drawing. Arrangement density of the fine particles 9 may vary depending on the coating conditions and how to prepare the fine particle dispersion, and the amount of electric currents flowing to the electrode spacing L may also vary

in accordance with this. In addition to the above formation by coating, also available as a method for dispersing the fine particles 9 to the electrode gap region obtained in (3) is, for example, a method in which a solution of an organic compound is coated on the substrate followed by thermal decomposition to form metal particles. In regard to materials feasible for vacuum deposition, the fine particles can be also formed by control of vacuum deposition conditions such as substrate temperature or by a means like vacuum deposition such as masked vacuum deposition.

(5) After this, the specimen obtained through the steps up to (4) is heated to a temperature higher than the softening point of the low-melting glass constituting the insulating layer 11, for example, to 450° C. if it is the lead oxide type low-melting glass, to carry out baking for about 20 minutes. By this procedure, the fine particles 9 arranged on the insulating layer 11 comprised of the low-melting glass penetrate into the low-melting glass, resulting in being included (or enclosed) into the insulating layer 11, or included to the extent that at least part of a particle is exposed from the insulating layer 11, and then fixed there.

Whether the fine particles 9 are brought into the state that all of them are included into the insulating layer 11 or the state that only part of a particle penetrates into the insulating layer 11 in the state that the surface remains exposed, may be adjusted by selecting the baking temperature in the step (5).

The higher the baking temperature is, the more readily the fine particles 9 are penetrated deeply into the insulating layer 11, and are included and fixed. A lower baking temperature may make it difficult for the fine particles 9 to penetrate into the insulating layer 11, and tend to make them fixed in the exposed form.

Some of the materials such as Pd listed in the above embodiment may be covered on their surfaces with oxide films as a result of heating in the above step (5), resulting in decrease in the amount of the electric current flowing to the electrode spacing L. Therefore, a step of pickling to remove the oxide film may be introduced if necessary.

In the present invention, the device may also be formed by bringing the fine particles 9 to be completely included into the insulating layer 11 and thereafter carrying out etching to bring part of each particle to be exposed.

Not only the device prepared according to the above preparation steps having the structure as illustrated in FIGS. 11(A)-11(E), but also the devices having the structure illustrated in FIG. 12 and FIGS. 13(a) and (b) can also exhibit good results.

Preparation processes in FIG. 12 will be described.

Electrodes 1 and 2 are formed on a substrate 4, on which a fine particle dispersion or a dispersion prepared by mixing low-melting frit glass into an organic metal compound solution is coated in the vicinity of the electrode spacing region L, followed by baking at a temperature higher than the softening point of the low-melting frit glass crystalline melting point to bring the fine particles to be included into an insulating layer 11 comprised of the low-melting glass, or bring at least part thereof to be exposed, and then fixed. Here, the baking temperature set to a higher degree (as exemplified by 650° C. enables the smoothing of the insulating layer 11 to make a continuous film.

In the figure, the insulating layer 11 may preferably be formed to have a film thickness of from several ten angstroms to several μm in approximation.

Here, a liquid coating insulating layer (as exemplified by Tokyo Ohka OCD, a SiO_2 insulating layer) may be used in place of the low-melting frit glass.

In the instance where the liquid coating insulating layer is used, it is also possible to obtain the electron-emitting device of the present invention in the following manner: First, the insulating layer 11 containing the fine particles 9 is built up on the substrate 4 according to liquid coating. Namely, it can be obtained by coating the fine particles mixed and dispersed in a liquid coating preparation, on a substrate by spin coating, dip coating or the like.

Next, electrodes are formed on the insulating layer 11 according to the above processes such as vacuum deposition to make up an electron emission device.

Taking said process, the fine particles are coated on the substrate in the state that they are mixed and dispersed in the liquid coating preparation or the like for obtaining the insulating layer, and therefore, even after the coating and baking, they remain dispersed in a good state in the film formed by coating the liquid coating preparation for obtaining the insulating layer. Accordingly, the fine particles suffer less agglomeration, and can be uniformly dispersed in the insulating layer obtained by the liquid coating preparation.

Also, since in the present structure the insulating layer containing fine particles is first formed on the substrate, the substrate surface before formation of the insulating layer is usually a uniform surface without any particular pattern or roughness. Accordingly, since the insulating layer containing the fine particles in its uniform surface is formed by coating and baking, there is no non-uniformity in the film thickness or fine particle dispersion owing to coating unevenness at the part of the pattern or roughness, so that a support layer in which the fine particles are dispersed can be uniformly formed on the substrate surface. Obtaining the insulating layer that is uniform like this can make small the irregularity or the like in device characteristics when a number of electron-emitting devices are provided on the same substrate.

Moreover, although in the present structure an in-air heating step at about 400° C. or more becomes necessary, for example, when the oxide type insulating layer is formed using the liquid coating preparation, the electrodes themselves do not pass through the heating step because the insulating layer formation heating is carried out before formation of the electrodes. Therefore, no account is required to be taken for the thermal oxidation of electrodes or thermal diffusion with respect to the insulating layer, thus enabling expansion of the range of selection for electrode materials.

Accordingly, the materials may be appropriately selected depending on the conditions such as dielectric strength, thermal resistance, workability, oxidation resistance, life, specific resistance, and amount of electric current that can be taken out. The materials for the insulating layer may include, as previously described, SiO₂, MgO, TiO₂, Ta₂O₅ and Al₂O₃, or a laminate or mixture of any of these. The film thickness may be from about 10 angstroms to several μm or so, which is the thickness necessary for the fine particles 9 to be dispersed and fixed.

The electron-emitting device may also have the structure as illustrated in FIG. 13(a) and 13(b).

In the electron-emitting device illustrated in FIG. 13, a fine particle dispersion prepared by mixing the low-melting frit glass for the insulating layer 11 is coated (here, carried out in the same manner as described in relation to FIG. 12), and thereafter the insulating layer 11 is formed into a discontinuous island-shaped film by setting the baking temperature to somewhat lower degree (for example, about 500° C.).

In the electron-emitting device illustrated in FIG. 13, the insulating layer 11 does not entirely cover the electrode

In addition, in the above steps 1) to 5), the low-melting glass may be used as the material for the insulating layer 11 and, after step 5) in FIG. 14E, the specimen may be baked at a temperature higher than the softening point of the low-melting glass, so that the fine particles 9 can be further firmly fixed in the insulating layer 11 comprised of the

low-melting glass. This makes it possible to provide a further stable electron-emitting device.

The electron-emitting device of the present invention may also comprise those as illustrated in FIGS. 15(a) and (b) and FIGS. 16(a) and (b).

In FIG. 15, the numeral 12 denotes a substrate comprising metals 13 such as Ag, Ba, Pb, W and Sn or metal oxides 13 such as BaO, PbO and SnO₂ deposited in porous glass. The numerals 1 and 2 denote electrodes provided on the substrate.

Usable as the above porous glass are Vycor glass available from Corning Glass Works or porous glass MPG available from Asahi Glass Co., Ltd., and those having a pore size of from 40 angstroms to 5 μ m, more preferably having a pore size of from 100 angstroms to 0.5 μ m. Fine particles of metals or metal oxides of the size equal to or smaller than the pore size are deposited in the pores. The present embodiment may not be limited to the porous glass, and may be worked using those obtained by roughening the glass surface with an aqueous hydrofluoric acid solution or other porous insulating substrates.

Bringing metals to be deposited and fixed in the pores of porous glass can be achieved by commonly available methods as exemplified by a method in which porous glass is impregnated with an aqueous solution of a nitrate such as AgNO₃, Ba(NO₃)₂ and PbNO₃ or an aqueous sulfuric acid solution, followed by drying and thereafter baking in a reducing atmosphere. To deposit the metal oxides, the deposited metals may be baked at a suitable temperature and in an atmosphere of oxygen.

In bringing the metals or metal oxides to be projected from the surface of porous glass, the glass surface may be treated for 1 minute with a hydrofluoric acid solution, followed by washing and drying. A desired substrate 12 can be thus prepared.

The above substrate 12 may more preferably have a thickness of 0.5 μ m or more because of the roughness on the surface of porous glass.

In FIGS. 16A and 16B, the numeral 14 denotes a glass substrate commonly called colored glass, which is glass that contains metal colloid fine particles 15. The numeral 1 or 2 denotes an electrode provided on the substrate. The metal colloid fine particles in the colored glass may suitably have a particle diameter of from 20 angstroms to 6,000 angstroms, more desirably from 100 angstroms to 2,000 angstroms. Also, the density of the fine particles, though variable depending on the particle diameter or materials for the fine particles, may suitably be in such a state that particles are spatially apart and electrically connected in the vicinity of a drive voltage. To make such colored glass, it can be readily prepared by a common, often used technique, namely, a method in which colorant raw materials such as AuCl₃ and AgNO₃ are dissolved in main components of the glass, which is then subjected to heat treatment for 10 to 20 minutes at temperatures of from 600° C. to 900° C. to deposit gold colloid or silver colloid fine particles in the glass. In the substrate prepared according to such a commonly available method, the metal fine particles are little deposited out of the glass surface, and therefore have good smoothness of the substrate surface on which the electrodes are formed, thus bringing about the advantage that the electrodes in this device can be made to have a smaller thickness.

In this device, after the metal fine particles were deposited in the glass, the substrate surface may also be treated with an aqueous hydrofluoric acid solution in the same manner as in the device described in relation to the above FIG. 15 so

that the metal colloids may be protruded in a large number from the glass substrate surface, thus obtaining the effect as aimed in the present invention.

The present invention further provides an electron-emitting device characterized by a device structure, comprising a semiconductor layer formed between opposing electrodes, and fine particles further arranged in a dispersed state on said semiconductor layer.

In the electron-emitting device of the present invention, application of a voltage between the electrodes brings about emission of electrons from the fine particles which are conductive.

Taking such a device structure not only can solve the problems involved in the prior art previously discussed, but also can provide an electron-emitting device capable of obtaining emitted electric currents with a low electric power and in a high density.

Description will be made below on the basis of FIG. 17.

In the figure, electrodes 1 and 2 are provided on a substrate 4, giving minute spacing to form a discontinuous electron-emitting region comprising fine particles 9 dispersed between them. The numeral 16 denotes a semiconductor layer formed at least at an electrode spacing region L.

FIG. 18 is a diagrammatical cross section in the C-D direction in FIG. 17. In the figure, the kind, particle diameter and spacing between fine particles on the substrate 4 are as described in relation to FIG. 8.

A method for preparing of the device illustrated in FIG. 17 will be described below.

FIGS. 19(A) to (C) illustrate cross sections of a device for each preparation step.

- (1) The surface of a substrate 4 comprised of glass or ceramics is degreased and cleaned.
- (2) On the insulating layer obtained in (1), electrodes 1 and 2 are formed according to vacuum deposition, photolithoetching, lifting-off, printing, or the like process.
- (3) Next, the fine particles 9 are coated on the electrode gap region obtained in (2). A dispersion of fine particles are used in the coating. Fine particles and an organic binder to promote dispersion of the fine particles are added in an organic solvent comprised of butyl acetate, alcohol, ketone or the like, followed by stirring or the like to prepare the dispersion of fine particles. Usable as the organic binder are butyral resins, acrylic resins, vinyl chloride-vinyl acetate copolymers, phenol resins, nylons, polyesters and urethanes.

Here, an example of methods for preparing the dispersion of the fine particles is set out below.

Fine particles, SnO_2	1 g
(fine particle diameter: 100 to 1,000 angstroms)	
Organic solvent, MEK (methyl ethyl ketone): cyclohexane = 3:1	1,000 cc
Organic binder, butyral	1 g

The above materials were stirred in a paint shaker for three hours with glass beads to make a dispersion.

This fine particle dispersion is coated on the surface of a specimen according to dipping, spin coating or the like process, and then baking is carried out for about 10 minutes at a temperature at which the solvent or the like may be evaporated and also the organic binder is carbonized to give a semiconductor layer, for example, at 250°C . Thus the semiconductor layer 16 and the fine particles 9 are arranged in the electrode spacing L. Of course, the semiconductor layer 16 and the fine particles 9 are arranged on the whole surface of the specimen, but no difficulty is brought about as

In addition to the above formation by coating, also available as a method for dispersing the fine particles 9 to the electrode gap region obtained in (2) is, for example, a method in which a solution of an organic compound is coated on the substrate followed by thermal decomposition to form metal particles. As an example, a solution is prepared using materials shown below:

In addition to the above formation by coating, also available as a method for dispersing the fine particles 9 to the electrode gap region obtained in (2) is, for example, a method in which a solution of an organic compound is coated on the substrate followed by thermal decomposition to form metal particles. As an example, a solution is prepared using materials shown below:

This Pd organic metal compound solution is coated, followed by heating, so that the fine particles 9 comprising Pd and the insulating layer 16 can be obtained.

The semiconductor layer 16 comprises a film mainly constituted of the carbon obtained by the baking. This is a semiconductor layer having an electrical specific resistance of about 1×10^{-3} ohm.cm or more.

In the specimen obtained according to the above steps, the thickness of the semiconductor layer 16 becomes smaller than the particle diameter of the fine particles 9. In other words, it has the structure that the fine particles 9, though embedded in the semiconductor layer 16, are fixed in the manner that they are partly protruded (FIG. 18).

In the embodiment having been described above, the fine particles 9 have the structure that they protrude from the semiconductor layer 16. Here, the fine particles 9 may be covered with a carbon film obtained by further coating only the organic binder solution on the surface of this device followed by baking, so that there can be given the structure that the fine particles 9 are included into the semiconductor layer 16 as illustrated in FIG. 20.

The ratio of carbon to fine particles in the coating solution may be changed to increase the carbon, and also the amount of coating may be increased, so that there can be also given the structure that the fine particles 9 are included into the semiconductor layer 16 or at least part thereof has protruded from the semiconductor layer as illustrated in FIG. 21.

The devices having been described above have the feature that the production steps can be simplified since the semiconductor layer 16 is formed in the same step as for arrangement of the fine particles 9.

It is also possible to prepare the semiconductor layer 16 from materials other than the carbon, namely, semiconductor materials obtained by coating or printing and baking, as exemplified by a solution containing Si, Ge, Se or the like. Accordingly, a semiconductor layer having desired characteristics can be obtained by selecting the conditions for the preparation and coating of the solution of these materials and for the baking. Also in using these semiconductor layers, there is retained the feature that the fine particles can be arranged in the same step.

The electron-emitting device of the present invention may also comprise an electron-emitting device having the structure as shown in FIG. 22.

A method of preparing the electron-emitting device illustrated in FIGS. 23A-23D will be described. Cross sections

of a device are illustrated in succession to describe below an example of the preparation method.

- 1) The surface of a substrate 4 is degreased and cleaned.
- 2) On the substrate obtained in 1), formed is a semiconductor layer 16 obtained by vacuum deposition, coating or printing and baking.

Usable as the above semiconductor layer are an amorphous silicon semiconductor film or crystallized silicon semiconductor film obtained by vacuum deposition, a compound semiconductor film, and a semiconductor film obtained by coating or printing and baking.

For example, there can be formed a hydrogenated amorphous silicon (A-Si:H) semiconductor layer obtained by plasma CVD. This semiconductor layer has a film thickness of approximately from 50 angstroms to 10 μm .

- 3) Electrodes 1 and 2 are provided in the same manner as in (2) in FIG. 19B.

- 4) Fine particles 9 are provided in the same manner as in (3) in FIG. 19C. It is preferred to decrease the amount of carbon in the coating solution or reduce it to zero to make small the thickness of the carbon film semiconductor layer formed at the electrode spacing region L. This is because the effect of the semiconductor layer 16 can be better brought out by allowing an electric current I_f flowing to the electrode spacing L to flow to the semiconductor layer 16 and the fine particles 9 as much as possible.

In the device having such structure, it is also possible to use fine particles feasible for vacuum deposition. With a material applicable to vacuum deposition, the fine particles can be formed by control of vacuum deposition conditions such as substrate temperature or by a means like vacuum deposition such as masked vacuum deposition.

In the electron-emitting device obtained according to the above 1) to 4), the semiconductor layer and the fine particles are each formed in a separate step, resulting in a greater degree of freedom in the conditions for forming the semiconductor layer. Accordingly, it becomes more possible to adjust characteristics of the semiconductor layer 16. For example, changing the amount of an impurity dope and selecting suitable conditions for formation in forming a semiconductor makes it able to readily adjust the electrical resistance of the semiconductor layer 16. Accordingly, it becomes feasible to adjust the amount of the electric current I_f flowing to the device, thus bringing about the feature that it becomes feasible to adjust the drive voltage of the device.

In the electron-emitting device of the present invention, the substrate itself may also comprise a semiconductor substrate that replaces the semiconductor layer 16. FIG. 24 illustrates a cross section of the device of this embodiment. As the semiconductor substrate 17, there can be used substrate materials having desired characteristics, as exemplified by Si wafers. Usable as methods for obtaining the semiconductor substrate having the desired characteristics are ion implantation to a semiconductor substrate or insulator substrate and the like methods.

This method enables adjustment of the specific resistance only at desired areas on the same plane. For this reason, in instances where electron-emitting devices are integrated in a high density, the leakage current among adjacent devices can be made small and the crosstalk can be decreased. Because of the arrangement on the same plane, this method further has the feature that no trouble such as disconnection may occur owing to poorness in step coverage on the stepped ends of the electrodes.

FIG. 25 is a cross section explanatory of still another electron-emitting device of the present invention. The respective materials are constituted in the manner as

in the insulating layer 5 forming a stepped portion are arranged at the electrode spacing 6 formed between the electrodes 1 and 2 whose end portions oppose each other (but without overlap) at the stepped portion, where electrons are emitted from the fine particles 9 by applying a voltage between the electrodes 1 and 2.

An example of preparation methods will be described below in relation to FIGS. 28(a), (b) and (c).

First, the insulating layer 5 containing the fine particles 9 is built up on the substrate 4 by liquid coating or a like process [[see FIG. 28(a)]] (see FIG. 28(a)).

Next, the insulating layer 5 is etched by photolithoetching so that a stepped portion is given substantially at the middle portion of the substrate 4 [[see FIG. 28(b)]] (see FIG. 28(b)).

Then the electrodes 1 and 2 are deposited on the insulating layer 5 and the substrate 4 in such a manner that at least part of the sidewall of the stepped portion may not be hidden, thus forming the electrode spacing 6 [[see FIG. 28(c)]] (see FIG. 28(c)).

The electron-emitting device of the present invention can be obtained according to the above process. The present device may be placed in a vacuum container, a voltage may be applied to the electrodes 1 and 2, and a lead-out electrode plate (not shown) may be disposed so as to oppose at the top surface of the device, to which a high voltage is applied, whereupon electrons are emitted from the vicinity of the electrode spacing 6.

In this figure, the materials for and thickness of the electrodes, materials for the fine particles concerned with the electron emission and materials for and thickness of the insulating layer are as described in relation to FIG. 1.

It can be confirmed that an electron-emitting device comprising electrodes 1 and 2 formed partly overlapping as illustrated in FIG. 29(c), though having a slight difference in the electrode spacing, can also give good results.

In the device illustrated in FIG. 29(c), an electrode 1 is first deposited and formed on a substrate 4 [[see FIG. 29(a)]] (see FIG. 29(a)). Thereafter an insulating layer 5 containing fine particles 9 and an electrode material 2c are deposited [[see FIG. 29(b)]] (see FIG. 29(b)), and an electrode 2 and electrode spacing 6 are formed by photolithoetching, thus forming an electron-emitting device [[see FIG. 29(c)]] (see FIG. 29(c)).

The present invention also provides an electron emission device as illustrated in FIG. 30, which is another embodiment of the electron-emitting device described in relation to FIG. 28 and at the same time a preferred embodiment of the electron-emitting device illustrated in FIG. 1.

The electron-emitting device illustrated in FIG. 30 comprises a substrate provided thereon with insulating layers interposing the face on which fine particles are dispersed, a stepped portion formed between an end portion of the insulating layer and the top surface of the substrate, and an electrode provided each on the top surface of said insulating layer and on the top surface of said substrate; an end of each electrode being positioned at an upper end or lower end of said stepped portion in such a manner that said electrode may not come into contact with the face on which the fine particles are dispersed; and electrode spacing being formed between said electrode ends, where electrons are emitted by applying a voltage between these electrodes.

In FIG. 30, the numeral 1 and 2 denote electrodes for obtaining electrical connection; 4, a substrate; 5a, an insulating layer on the substrate 4; 9, fine particles on the insulating layer 5a; 5b, an insulating layer to cover the fine particles; and 6, electrode spacing between the electrodes 1 and 2.

In FIG. 30(d), the electron-emitting device of the present invention is a device in which the fine particles 9 interposed

A preparation method thereof will be described below.

Next, the insulating layer 5b is built up or deposited on the insulating layer 5a and the fine particles 9 by liquid coating or vacuum deposition or the like process so that it may cover the fine particles 9 [[see FIG. 30(b)]] (see FIG. 30(b)).

The insulating layers **5a** and **5b** interposing the fine particles are further formed by photolithoetching so that the stepped portion can be given substantially at the middle of the substrate **4** [[see FIG. 30(c)] [see FIG. 30(c)].

Thereafter, the electrodes 1 and 2 are deposited on the insulating layer 5b and the substrate 4 in such a manner that at least part of the sidewall of the stepped portion and the fine particles 9 may not be hidden and also no electric short may be caused, to form the electrode spacing 6 [[see FIG. 30(c)] (see FIG. 30(c)).

The electron-emitting device of the present invention can be obtained according to the above process. The present device may be placed in a vacuum container, a voltage may be applied to the electrodes 1 and 2, and a lead-out electrode plate (not shown) may be disposed so as to face the top surface of the device, to which a high voltage is applied, whereupon electrons are emitted from the vicinity of the electrode spacing 6.

The present invention may still also be embodied for the electron-emitting region 3 by forming an electron-emitting layer 3a and electron-emitting bodies 3b.

For example, as illustrated also in FIG. 31, this is an electron-emitting device having the structure that, for example, the embodiments of FIG. 3 and FIG. 5 previously described are combined.

In FIG. 31, the electron-emitting device of the present invention is a device comprising a laminate comprising an insulating layer 5 held between a pair of electrodes whose end portions oppose each other, wherein the electron-emitting layer 3a is included into the insulating layer 5 in such a manner that the sidewall face of the electron-emitting layer 3a may be disposed along the sidewall face of the insulating layer 5 formed at the opposing portion at which the electrodes 1 and 2 oppose each other, and the electron-emitting bodies 3b are further disposed at the surface of said sidewall, where electrons are emitted by applying a voltage between the electrodes 1 and 2.

The materials and methods for forming the device are as described previously.

Besides taking the structure as illustrated in FIG. 31 to form the electron-emitting region 3, it is also desirable to, as shown in FIG. 33, form a stepped portion 18 with an insulating layer 5 containing fine particles (electron-emitting materials) 9 and at the same time provide electron-emitting bodies 3b on the side surface of said stepped portion.

Alternatively, as shown in FIG. 35, fine particles (electron-emitting materials) 9 may be arranged on an insulating layer 5a, the fine particles are further covered thereon with an insulating layer 5b to form a stepped portion, and electron-emitting bodies 3b may be further arranged on the side surface of said stepped portion to form an electron-emitting region.

In the present invention, the device may also comprise an electron-emitting region obtained by three or more of its formation methods as shown in FIG. 36.

Incidentally, in the case where the fine particles are used as the electron-emitting bodies 3b dispersed on the side surface or the electron-emitting materials 9 contained in the insulating layer as described above, it was confirmed that employment of two or more kinds of different materials as said fine particles enables better control of the characteristics as the electron-emitting device.

Usable as materials for the fine particles are the materials same as those described in relation to FIG. 8. Selecting appropriately two or more kinds of different materials among those materials as occasion demands and using them as the fine particles makes it possible to not only achieve electron emission but also improve or control the characteristics of intended electron-emitting devices.

For example, since in the electron-emitting device of the present invention an electric current in the direction of electrodes is indispensable for electron emission, it is possible to lower the drive voltage of the device by incorporating fine particles of relatively low resistance nature (for example, incorporating Pd or Pt fine particles in SnO_2 fine particles).

It can be also expected to increase electron emission by adding to Pd fine particles, low work function materials as exemplified by LaB_6 or materials having a large coefficient of secondary electron emission as exemplified by an AgMg alloy.

The present invention can be also effective not only for the embodiment using the fine particles of two or more of different materials, but also for the instance where the fine particles, even though comprised of one kind of material, are constituted of two or more kinds having difference only in physical parameters such as average particle diameter and shapes.

For example, the particle diameter may be made to comprise two kinds, one of which is so fine (as exemplified by a particle diameter of about 100 angstroms) that the effect of electric field emission can be greatly exhibited, and the other of which is relatively so large (as exemplified by a particle diameter of about 4,000 angstroms) as to be contributory only to electrical conductivity, so that the former can realize an increase in the amount of electron emission, and the latter, driving with a low voltage.

It is of course also possible to utilize the materials by making combination both of the above-described two or more kinds of different materials and two or more kinds having difference in physical parameters as in particle diameter.

To form the fine particles by dispersion, the most simple and convenient is a method in which a dispersion of fine particles comprising desired materials is coated on a substrate or the like by rotary coating, dipping or the like technique, followed by heating to remove a solvent, a binder and so forth. In this instance, adjusting the particle diameter of fine particles, content thereof, coating conditions, etc., enables control of the state of distribution of their dispersion.

There is no established theory as to the mechanism by which the electrons are emitted from the electron-emitting device according to the present invention, but it is presumed to be nearly as follows:

Presumed is the electric field emission because of the voltage applied to a narrow insulating layer gap, or the secondary electron emission occurring when the electrons emitted from electron-emitting materials are diffracted or scattered by the film of the island-like structure or the

The above apparatus making use of the electron-emitting device of the present invention will be described below in detail with reference to the drawings.

FIG. 39A is a partially cutaway perspective view to show the structure of a display panel.

FIG. 39A shows the structure of the display panel, in which VC denotes a vacuum container made of glass, and FP, part thereof, denotes a face plate on the display surface side. At the inner face of the face plate FP, a transparent electrode made of, for example, ITO is formed. At the further inner side thereof, red, green and blue fluorescent members (image forming members) are dividedly applied in a mosaic fashion, and provided with a metal back as known in the field of CRT. The transparent electrode, the fluorescent member and the metal back are not shown in the drawing 39A, but are shown in FIG. 39D. In FIG. 39D the face plate, FP, transparent electrode, TE and fluorescent member, FL are shown as three layers laminated in the order shown. The above transparent electrode is electrically connected to the outside of the vacuum container through a terminal EV so that an accelerating voltage can be applied.

The letter symbol S denotes a glass substrate fixed to the bottom of the above vacuum container VC, on the surface of which the electron-emitting device ED of the present invention is formed in arrangement (FIGS. 39B and 39C) with number $N \times$ lines 1. Herein, FIG. 39B shows an example wherein the devices in which electrodes 1 and 2 are juxtaposed on a surface of a substrate are arranged. Further, FIG. 39C shows an example wherein the devices in which electrodes 1 and 2 are laminated on a substrate are arranged. The group of electron-emitting devices are electrically parallel-connected for each line, and positive-pole side wiring 31 (or negative-pole side wiring 32) of each line is electrically connected to the outside of the vacuum container VC through terminals D_{m1} to D_{mN} (of terminals D_{m1} to D_{mN}).

A grid electrode (modulating electrode) GR is formed in a stripe between the substrate S and the face plate FP. The grid electrode (modulating electrode) GR is provided in the number of N, falling under right angles with the line of the electron-emitting device. Grid holes Gh are provided in each electrode, through which electrons are transmitted. The grid holes Gh may be provided one by one corresponding with each electron-emitting device as shown in FIG. 39A, or the number of minute holes may alternatively be provided in a mesh form.

The respective grid electrodes (modulating electrodes) GR are electrically connected to the outside of the vacuum container VC through grid electrode terminals G_1 to G_N .

In the present display panel, the lines of the electron-emitting devices in the number of l and the lines of the grid electrodes (modulating electrodes) in the number of N constitute an XY matrix. Synchronizing with the successive driving (scanning) of the lines of electron-emitting devices line by line, modulating signals allotted to one line of an image are simultaneously applied to the lines of grid electrodes (modulating electrodes) in accordance with information signals. Thus, the irradiation with each electron beam to the fluorescent member can be controlled and the image is displayed line by line.

The image display apparatus as described above can be an image display apparatus capable of obtaining a displayed

image particularly with a high resolution, free of luminance unevenness and with a high luminance, and having a facility of manufacturing a long life, because of the advantages attributable to the electron-emitting device of the present invention as previously described.

EXAMPLES

Specific examples of the present invention will be described below.

Example 1

FIGS. 3(A) and (B) are a flow sheet illustrating an example for a method of preparing the electron-emitting device of the present invention.

In FIGS. 3(a), (b), the numeral 4 denotes a glass substrate; and 1, a nickel electrode of 500 angstroms thick.

SiO_2 was vapor deposited to form an insulating layer 5a of 1,000 angstroms thick. Au was vapor deposited as an electron-emitting layer 3a to have a thickness of 500 angstroms, and an insulating layer 5b was also formed in the same manner as for 5a, thus bringing these three layers into lamination.

Then these were partly laminated on the electrode 1 as illustrated in FIG. 3(a), along the pattern of the electrode 1, followed by patterning. Next, Ni was laminated as an electrode 2 with a film thickness of 5,000 angstroms.

As illustrated in FIG. 3(b), the electrode 2 as subjected to patterning by usual photolithographic process along the patterns of the electrode 1, insulating layer 5a, electron-emitting layer 3a and insulating layer 5b. As illustrated in the figure, the electrodes 2a and 2b were electrically separated, and here the area at which the electrode 2b and electrode 1 overlap was made as small as possible.

Applying a voltage of 20 V between the electrode 2a and 2b, there was obtained emission of an electron beam 7 of 0.3 μA per 1 mm length of width of the electrode 2a in the direction vertical to the paper surface.

As to the electron-emitting layer 3a, usually it may show an island structure similar to the small island structure among narrow cracks in the conventional film prepared by forming, if its film thickness is 100 angstroms or less. However, it is presumed that even if the film thickness increases to give a continuous film, the electrodes 1 and 2b are electrically insulated, and thus the layer acts similarly to the island structure.

Example 2

In FIG. 4, the numerals 1 to 5 denote the same as in FIG. 3. In this figure, the numeral 8 denotes an intermediate layer, which is interposed between the insulating layer 5b and electrode 2 to constitute a multi-layer electrode. In the present Example, subsequent to the formation of the insulating layer 5b, a step to vapor-deposit LaB_6 to a thickness of 1,000 angstroms followed by patterning was added to the preparation steps in Example 1. The electrode 2 was also formed by using Ni with a thickness of 5,000 angstroms as in Example 1.

Applying a voltage of 20 V between the electrode 2a and 2b of the device thus obtained, there was obtained emission of an electron beam 7 of 0.5 μA per 1 mm length of width of the electrode 2a in the direction vertical to the paper surface.

Example 3

FIGS. 6(A) and (B) are a flow sheet illustrating an example for a method of preparing the electron-emitting device accord-

ing to the second embodiment of the present invention. In FIGS. 6(a), (b), the numeral 4 denotes a glass substrate.

An insulating layer 5a was formed with SiO_2 in 1,500 angstrom thickness; an electron-emitting layer 3a, with Pd in 250 angstrom thickness; and an insulating layer 5b, with SiO_2 in 500 angstrom thickness, each of which layers were obtained by vacuum deposition and thereafter, as illustrated in FIG. 6(a), etched to have a stepped shape to effect patterning. Next, electrodes 1 and 2 are deposited. The electrodes are, as illustrated in FIG. 6(b), deposited on the insulating layer 5a and 5b and the stepped portion formed by the electron-emitting layer 3a with use of Ni with a thickness of 1,000 angstroms. In this occasion, generally the electrode 1 will not come into contact with the electron-emitting layer 3 if the thickness of the electrode is made smaller than the height of the stepped portion of the insulating layer 5a, i.e., the step coverage is made poor, and also the electrode spacing 6 can be made narrower if the insulating layer 5b is made thinner.

The electron-emitting device obtained according to the above process was placed in vacuum, a voltage of 1 kV was applied using a lead-out electrode (not shown) provided at an upper area in the drawing, and a direct current voltage of about 12 V was applied between the electrodes 1 and 2, resulting in emission of electrons from the electron-emitting region 3.

Example 4

(See FIG. 2.) On a glass substrate 4, an insulating layer 5 was deposited using SiO_2 to a thickness of 2,000 angstroms. This was etched to have a stepped shape to effect patterning. Next, electrodes 1 and 2 were deposited with Ni in 1,000 angstroms thickness by vacuum deposition with masking to desired shapes. Here, the step coverage by vapor deposited Ni at the stepped portion was generally made poor, and the electrode spacing 6 was formed in a space of about 1,000 angstroms. Fine particles were made to be fixed here as electron-emitting bodies 3b. The fine particles are obtained, for example, by the following manner. Namely, prepared is a solution of fine particles of metals such as Pd, having a particle diameter of several 100 angstroms as materials serving as the electron-emitting bodies 3b. This solution was coated by spin coating, and baked at a temperature of about 300° C. to fix the fine particles to the electrode spacing region. The resulting device was able to emit electrons by driving it as in Example 3.

Example 5

In the constitution in FIG. 8, formed on a soda lime glass substrate 4 was an insulating layer 11 comprised of a lead oxide type low-melting glass coating film.

Pt electrodes 1 and 2 were further formed thereon with a thickness of 1,000 angstroms, $L=0.5 \mu\text{m}$ and $W=300 \mu\text{m}$, and Pd, as fine particles 9, of several hundred angstroms in particle diameter were further arranged in a dispersed state between said electrodes.

The Pd fine particles 9 were arranged by spin coating (3,000 rpm; coating was repeated five times), using a butyl acetate solution (Catapaste CCP-4230, available from Okuno Seiyaku Kogyo) containing an organic palladium compound in an amount of about 0.3% in terms of Pd metal, and treated by heating at 250° C. They were then baked for 20 minutes at 450° C. to bring the fine particles to be included into the insulating layer 11.

Here, the amount of an electric current flowing to the electrode spacing L was about 5 $\mu\text{A}/5\text{V}$. This specimen was

subjected to pickling using an aqueous 5 to 10 vol. % HCl solution, resulting in the amount of electric current of 250 $\mu\text{A}/5\text{V}$.

The specimen prepared according to the above process was placed under vacuum of 10^{-5} Torr or more, and a voltage was applied between the electrodes 1 and 2 as described above. As a result, an electric current V_f flowed on the surface of the inside of the insulating layer 11 or through the fine particles 9, and a stable electron emission was confirmed when a voltage was applied allowing a lead-out electrode (not shown) to serve as the anode. The electron emission was also confirmed in regard to a specimen to which no pickling was applied.

Results of measurement on the electron-emitting device prepared in the present Example are shown in Table 1. Swing of the emitted electric current is indicated with a value obtained by dividing the amount of change ΔI_e in the amount of the emitted electric current of 1×10^{-3} Hz or less by the emitted electric current I_e and multiplying it by 100, i.e., $\Delta I_e/I_e \times 100$.

TABLE 1

V_f Device drive voltage	I_e Emitted current	Efficiency (Emitted current I_e / Device current I_d)	Life*	Swing of emitted current
Present Example: 30 V	μA 0.8	8×10^{-3}	100 hrs or more	10%

*Life: The period in which the emitted electric current comes to 50% or less.

The above results, as compared with the results of measurement of a surface conduction electron-emitting device comprised of ITO materials that required the forming of the conventional technique (drive voltage of the device: 20 V; emitted electric current: 1.2 μA ; efficiency: 5×10^{-3} ; life: 35 hours; swing of emitted electric current: 20 to 60%), can tell the following:

The electron-emitting device of the present Example is stable and of long life, and shows high characteristics in the electron-emitting efficiency.

Example 6

Example 5 was exactly repeated except that the baking for 20 minutes at 450°C . was replaced by complete baking for 2 hours at 490°C ., to carry out an experiment.

The device obtained by the above experiment gives a device in which all the fine particles 9 are penetrated into the insulating layer 11 (FIG. 9).

The same measurement as in Example 5 was made on this electron-emitting device to obtain the same electron emission as in Example 5, but it tended to have a longer life and show further decreased swing of the emitted electric current.

More specifically, the electron-emitting device in which the fine particles are included into the insulating layer as in the present Example 6 is characterized by being more improved in the life and the swing of emitted electric current in addition to the effect obtainable in Example 5.

Example 7

Example 5 was exactly repeated except that the baking for 20 minutes at 450°C . was replaced by baking for 10 minutes at 420°C .

The device obtained by the above experiment gives a device as shown in FIG. 10. The electron-emitting device in which the fine particles are slightly penetrated into the insulating layer brought about an electron-emitting device having more improved emitted electric current and emitted current efficiency (I_e/I_p) in addition to the effect obtainable in Example 4.

Example 8

The surface of the insulating layer 11 at the electrode spacing L of the electron-emitting device obtained in Example 6 was etched using an aqueous 5 Vol. % Hf solution to bring the fine particles 9 to expose from the insulating layer 11, so that there was obtained a device having the same structure as in the above Example 7.

Example 9

Using a substrate 12 comprising porous glass having a pore size of 80 to 1,000 angstroms in which gold fine particles were deposited to have a device resistance of from 1 megaohm to 10 megaohms, there was given an electron-emitting device of the present invention (FIG. 9).

Measurement on said device was carried out in the same manner as in Example 5. Results are shown in Table 2.

TABLE 2

V_f Device drive voltage	I_e Emitted current	Efficiency (Emitted current I_e / Device current I_p)	Life*
Present Example: 25 V	μA 1.0	2×10^{-3}	1,000 hrs or more

*Life The period in which the emitted electric current comes to 50% or less.

It was revealed from the above results that the electron-emitting device of the present invention becomes an electron-emitting device that is stable (i.e. small in the swing of the emitted electric current) and of long life and has a high electron emission efficiency as compared with a conventional device obtained by forming of gold (device drive voltage of: 16 V; emitted current: 0.8 μA ; efficiency: 1.2×10^{-3} ; life: 35 hours; swing: 20 to 60%). After the experiment for electron emission, the degree of device deterioration was observed by using a scanning type electron microscope, but there was seen little change in the diameter or distribution of the fine particles of gold present between the electrodes. However, the device obtained by forming of gold showed an extreme deterioration at the high resistance part discussed in the prior art.

The device according to the present Example 9 was able to be readily integrated with less irregularities between devices even when a number of the devices were formed on the same substrate.

Example 10

Referring to FIG. 16, obtained was an electron-emitting device comprising a colored glass (golden red glass) substrate 14 having gold colloids.

The same measurement as in Example 5 was made on said electron-emitting device. Results obtained are shown in Table 3.

TABLE 3

V_d Device drive voltage	I_e Emitted current	Efficiency (Emitted current I_e / Device current I_d)	Life*
Present Example: 32 V	μA 0.6	2×10^{-2}	2,000 hrs or more

*Life: The period in which the emitted electric current comes to 50% or less.

As will be seen also from Table 3, the electron-emitting device of the present Example is stable (i.e. small in the swing of the emitted electric current) and of long life and has a high electron emission efficiency. After the experiment for electron emission, the degree of device deterioration was also confirmed by using a scanning type electron microscope, but there was seen little change in the diameter or distribution of the fine particles of gold present between the electrodes. In contrast therewith, the conventional device obtained by forming of ITO shows an extreme deterioration at the high resistance part.

There was also obtained similar results in the case when, after fine particles are deposited in the glass, the substrate surface was treated with an aqueous hydrofluoric acid solution so that metal colloids may be protruded in a large number from the surface of the glass substrate, thus giving an electron-emitting device of the present invention.

Example 11

On a clean, quartz glass substrate of about 1 mm thick, a solution prepared by mixing an organic solvent (Catapaste CCP, available from Okuno Seiyaku Kogyo) containing an organic palladium compound with a SiO_2 liquid coating preparation (OCD, available from Tokyo Ohka Kogyo) to have a molar ratio of SiO_2 :Pd of about 5:1 was spin-coated with a spinner. Thereafter the resulting coating was baked for 1 hour at about 400°C . to obtain a SiO_2 insulating layer 11 having a film thickness of about 1,000 angstroms and containing Pd fine particles 9. After this step, the surface of the insulating layer 11 was etched using an aqueous hydrofluoric acid to bring the fine particles 9 to protrude from the insulating layer 11.

Next, on the SiO_2 insulating layer 11, a photoresist was formed by photolithography with a thickness of about $0.8\ \mu\text{m}$ in the shape giving an electrode spacing L. Further on the SiO_2 insulating layer 11 and said photoresist, a Ni thin film was deposited with a thickness of 1,000 angstroms according to the masking EB vacuum deposition that obtains shapes of electrodes. Thereafter the photoresist was peeled to carry out a lift-off step to remove unnecessary Ni thin film on the photoresist. Thus the shapes of the electrodes 1 and 2 and electrode spacing L as shown in FIG. 8 can be formed. In this instance, each dimension shown in FIG. 8 was set to be $[L=0.4\ \mu\text{m}]$ $L=0.8\ \mu\text{m}$, $W=300\ \mu\text{m}$ and $A=2\text{mm}$.

Electron emission characteristics of the electron-emitting device obtained according to the above process were measured to have revealed that there was obtained electron emission of, approximately, emitted electric current $I_e=1\ \mu\text{A}$ and emission efficiency $\alpha=5 \times 10^{-3}$ under the drive voltage $V_d=30\ \text{V}$ of the device. The life and the swing of the emitted electric current were in substantially the same level as those in Example 5.

Example 12

Example 11 was repeated but replacing the organic palladium compound by SnO_2 fine particles of 100 angstroms in average particle diameter, to obtain a similar electron-emitting device, and similar experiments were carried out. As a result there was obtained electron emission of substantially the same level as in Example 11.

Example 13

In the constitution as illustrated in FIG. 17, a semiconductor layer 16 of about 100 angstroms thick was formed on a soda glass substrate 4 by using a carbon film obtained from a calcined organic substance. Palladium fine particles of about 100 angstroms in diameter are dispersed in the semiconductor layer.

Electrodes 1 and 2 were also formed with Pt to have a thickness of 1,000 angstroms, a spacing of 0.8 μm , and a width of 300 μm .

Applying a voltage between the electrodes 1 and 2 prepared in the above example produced a flow of an electric current I_f through the semiconductor layer 16 and fine particles 19, and a stable electron emission was confirmed when a voltage was applied allowing an lead-out electrode to serve as the anode.

Comparison of examples of characteristics were made between the electron-emitting device prepared in the present Example, having a semiconductor, and a prior art surface conduction electron-emitting device comprised of ITO and requiring the forming, to obtain the results shown in Table 4. Swing of the emitted electric current is indicated with a value obtained by dividing the amount of change ΔI_e in the amount of the emitted electric current of 1×10^{-3} Hz or less by the emitted electric current I_e and multiplying it by 100, i.e., $\Delta I_e/I_e \times 100$ (%)

TABLE 4

V_f Device drive voltage	I_e Emitted current	Efficiency (Emitted current I_e / Device current I_f)	Life*	Swing of emitted current
Present Example: 15 V	4 μA	1×10^{-3}	800 hrs or more	15%
Device of forming of ITO: 20 V	1.2 μA	5×10^{-3}	35 hrs	% 20-60

*Life: The period in which the emitted electric current comes to 50% or less

As will be clear from Table 4, the surface conduction electron-emitting device of the present Example is characterized by being stable and of long life, showing a low drive voltage and a large emitted electric current.

Example 14

In the constitution illustrated in FIG. 22, an A-Si:H film was deposited on a glass substrate 4 by plasma CVD to have a thickness of 2,000 angstroms, thus giving a semiconductor layer 16. Electrodes 1 and 2 were formed with Pt to have a thickness of 1,000 angstroms, a spacing L of 0.8 μm , and a width W of 300 μm .

Pd, as fine particles 9, of several 100 angstroms in diameter were further arranged in a dispersed state between said electrodes.

The Pd fine particles 9 were arranged by spin coating (3,000 rpm; coating was repeated five times), using a butyl acetate solution (Catapaste CCP-4230, available from Okuno Seiyaku Kogyo) containing an organic palladium compound in an amount of about 0.3% in terms of Pd metal, and treated by heating at 250° C. The electron-emitting device prepared in the present Example, having a semiconductor, was evaluated in the same manner as in Example 13. As a result, it was able to obtain similar electron emission.

Example 15

In the constitution illustrated in FIG. 25, electrodes 1 and 2 were formed on a glass substrate 4 with Pt to have a thickness of 1,000 angstroms, a spacing L of 0.8 μm , a width W of 100 μm .

Fine particles were prepared in the same manner as in Example 14, and hydrogenated amorphous silicon was formed as a semiconductor layer 16 by plasma CVD to have a thickness of about 500 angstroms.

Thereafter the convexes on the semiconductor layer 16 were etched by ion milling.

The electron-emitting device prepared according to the above process was evaluated in the same manner as in Example 12 to have found that there is obtained similar electron emission. Particularly in the present Example, different from Example 14, the electron-emitting device in which the fine particles 9 were fixed in the semiconductor layer 16 had a tendency of stableness in electron emission in addition to the effect obtainable in Example 14.

Example 16

An electron-emitting device was obtained according to the previously described preparation steps (a) to (c) of FIG. 28.

More specifically, on a clean, quartz glass substrate of about 1 mm thick, a solution prepared by mixing an organic solvent (Catapaste CCP, available from Okuno Seiyaku Kogyo) containing an organic palladium compound with a SiO_2 liquid coating preparation (OCD, available from Tokyo Ohka Kogyo) to have a molar ratio of SiO_2 :Pd of about 5:1 was spin coated with a spinner. Thereafter the resulting coating was baked for 1 hour at about 400° C. to obtain a SiO_2 insulating layer 5 having a film thickness of about 1,500 angstroms and containing Pd fine particles 9 [[see FIG. 28(a)] (see FIG. 28(a))].

Next, the insulating layer 5 was etched by photolithoetching with use of an aqueous hydrofluoric acid solution to form a stepped portion of about 1,500 angstroms high at the middle of the substrate 4 [[see FIG. 28(b)] (see FIG. 28(b))].

Thereafter, Ni electrodes 1 and 2 of about 500 angstroms in film thickness were formed by deposition utilizing EB vacuum deposition in the manner that the stepped portion may not be completely covered.

In this instance, there is given the structure that the electrodes 1 and 2 oppose each other with certain spacing, across the side wall of the stepped portion of the insulating layer 5 containing the fine particles 9. This space is designated as electrode spacing 6 [[see FIG. 28(c)] (see FIG. 28(c))].

Electron emission characteristics of the electron-emitting device obtained according to the above process were measured to have revealed that there was obtained electron emission of, approximately, emitted electric current $I_e=2.5 \mu\text{A}$ and emission efficiency $\alpha=5 \times 10^{-3}$.

Example 17

According to the previously described preparation steps (a) to (c) of FIG. 29, prepared was an electron-emitting

Ni electrodes 1 and 2 of about 5,000 angstroms in film thickness was further formed by deposition utilizing EB vacuum deposition in the manner that the stepped portion may not be completely covered. A space thus formed is designated as electrode spacing 6 [[see FIG. 30(d)]] (see FIG. 30(d)).

Example 20

Example 21

Electron emitting bodies 3b were further provided on the surface of a side wall of the insulating layer in the same manner as in Example 19 [[see FIG. 33(d)] (see FIG. 33(d)).

Electron emission characteristics of the electron-emitting device obtained according to the above process were measured to have revealed that there was obtained electron emission of, approximately, emitted electric current $I_e=4\ \mu\text{A}$ and emission efficiency $\alpha=2\times 10^{-3}$, under applied device voltage $V_f=14\ \text{V}$ and lead-out voltage $V_a=1\ \text{kV}$.

Example 22

Example 21 was repeated except that the organic metal compound solution that formed the electron-emitting bodies 3b in Example 21 was replaced by a SiO_2 liquid coating preparation in which SiO_2 fine particles of about 100 angstroms in particle diameter were dispersed, to form a similar electron-emitting device. There were obtained substantially the same results as in Example 21.

Example 23

Similar results were obtained also when the organic metal compound solution employed to form the electron-emitting bodies 3b in Example 20 was replaced by a coating preparation in which SnO_2 fine particles of about 100 angstroms in particle diameter were dissolved by dispersion together with an organic binder.

Example 24

On a substrate a SiO_2 film is vacuum deposited to form an insulating layer 5a, on which Pd is vacuum deposited in a thickness of 500 angstroms (electron-emitting layer 3a) and further an insulating layer 5b is formed by vacuum deposition of a SiO_2 film [[see FIG. 34(a)]] (see FIG. 34(a)).

Next, the insulating layers 5a, 5b and electron-emitting layer 3a are etched to form a stepped portion 18 [[see FIG. 34(b)]] (see FIG. 34(b)).

Thereafter, Ni is applied by masking vacuum deposition in a thickness of 500 angstroms to form electrodes 1 and 2 [[see FIG. 34(c)]] (see FIG. 34(c)).

An organic palladium solution is further coated on the surface of the device substrate, followed by baking to provide electron-emitting bodies 3b on the sidewall of the stepped portion [[see FIG. 34(d)]] (see FIG. 34(d)).

The resulting electron-emitting device has the structure that electron-emitting materials are present only in the vicinity of the stepped portion in contrast with Example 20.

Good results were obtained as in Example 20.

Example 25

Example 24 was repeated to obtain an electron-emitting device, except that the Pd fine particles film of the electron-emitting layer 3a in Example 24 as replaced by a layer obtained by coating a Pd fine particles dispersed solution as shown in FIG. 35.

There was obtained the same electron emission.

Example 26

The same electron emission as in Example 20 was obtained also in a device in which as illustrated in FIG. 36 a Pd vapor-deposited film serving as an electron-emitting layer 3a was disposed in an insulating layer 5 containing electron-emitting materials 9 as Pd fine particles, a stepped portion was formed, and electron-emitting bodies 3b were further provided on the sidewall of the stepped portion by coating an organic palladium solution followed by baking.

Example 27

In the constitution illustrated in FIG. 37, on a glass substrate 4, titanium electrodes 1 and 2 were formed with a

As a method therefor, a SnO₂ dispersion (SnO₂: 1 g; solvent: MEK (methyl ethyl ketone)/cyclohexanone=3/1, 1.000 cc; butyral: 1 g) having a primary particle diameter of 80 to 200 angstroms was spin-coated, followed by heating. A Pd dispersion having a primary particle diameter of about 100 angstroms was further spin coated, followed by heating to obtain an electron-emitting device.

Thus, substantially the same electron emission is obtained even under the applied voltage of lower by approximately 5 volts than that of the device containing no Pd fine particles and solely comprised of SnO_2 . In this manner, the drive voltage was able to be lowered by the device containing different kind of fine particles.

In regard to the SnO_2 dispersion of Example 27, a dispersion of SnO_2 of 80 to 200 angstroms in particle diameter and a dispersion of SnO_2 of about 3,000 angstroms in particle diameter were prepared, and two kinds of the SnO_2 dispersions were coated in the same manner as in Example 27 but in one step for each dispersion, thus arranging fine particles in a dispersed state to obtain a electron-emitting device.

Thus, substantially the same electron emission is obtained even under the applied voltage of about 3 V lower than that of the device obtained by coating in two steps the dispersions of SnO_2 of 80 to 200 angstroms in particle diameter. In this manner, the drive voltage was able to be lowered by adding the particles having a larger particle diameter.

¹ Using each of the electron-emitting devices prepared in the above examples, image display apparatuses as shown in FIGS. 39A, 39B and 39C were prepared. Herein, a pitch of device wiring electrodes 33, wherein 33-a and 33-b constitute a pair, is 2 mm, a pitch in electron-emitting regions 30 is 2 mm. Face plate (FP) was located at 4 mm distance from substrate (S). Grid electrodes (GR) were located at 10 μ m distance from the surface of the electron-emitting device.

The voltage on the surface of the fluorescent member is set to be from 0.8 kV to 1.5 kV. In FIGS. 39B and 39C, a voltage pulse of 14 V is applied to a pair of device wiring electrodes 33-a and 33-b so that electrons are emitted from the plural electron-emitting devices arranged in linear fashion. The electrons thus emitted are brought under ON/OFF control of electron beams in accordance with information signals by applying a voltage to the group of modulating electrodes. The electrons drawn out by the modulating electrodes impinge against the fluorescent member under acceleration. The fluorescent member performs a line of display in accordance with the information signals. Next, a voltage pulse of 1' V is applied to the adjacent device wiring

electrode 33-a and 33-b to carry out a line of display as in the above. This operation is successively repeated to form a picture of the image. More specifically, having the group of electron-emitting devices serve as scanning electrodes, the scanning electrodes and the modulating electrodes for the XY matrix, and thus the image is displayed.

The electron-emitting device according to the present embodiment can drive in response to a voltage pulse of 100 picoseconds or less, and hence the displaying of an image in 1/30 second for one picture enables formation of 10,000 lines or more of scanning lines.

The voltage applied to the group of modulating electrodes (GR) is 0 V or less, or 30 V or more, under which the electron beams are OFF-controlled or On-controlled, respectively. The mount of electron beams continuously varies at voltages between 0 V and 30 V. Thus, it is possible to effect gradational display according to the magnitude of the voltage applied to the modulating electrode.

[Effect of the invention] Effect of the invention

As described above, according to the electron-emitting device of the present invention and the method for preparing the same, electron-emitting devices that can have stable structure even if the electrode spacing having the electron-emitting materials is made very narrow can be formed without applying the forming required in the prior art.

Accordingly, the electron-emitting devices prepared by the present invention are quite free from the difficulties conventionally accompanying the forming treatment, so that it becomes possible to manufacture the devices having less irregularities in characteristics, in a large number and with ease, bringing about great industrial utility.

The electron-emitting device obtained by the present invention can also be utilized in planar display devices in which the electron-emitting devices are mounted in a single plane and electrons emitted by applying a voltage are accelerated to stimulate phosphors to effect light-emission.

An electron-emitting device that is stabler and of longer life and also has a good efficiency can also be obtained by bringing the electrode constitution into a multi-layer constitution.

Also, the electron-emitting device in which the fine particles are fixed in the insulating layer is free of any move-

6. A method of fabricating an electron-emitting device which comprises a pair of electrodes and a layer disposed between the electrodes, the method comprising the steps of:

disposing the pair of electrodes in first and second regions on a substrate, respectively; and

providing the layer between the regions, the layer comprising a metal and a semiconductor.

7. The method of Claim 6, wherein the metal is Pd.

8. The method of Claim 6 or 7, wherein the semiconductor is selected from the group consisting of carbon and SnO₂.

9. A method of fabricating an electron-emitting device, comprising the steps of:

disposing a pair of electrodes in first and second regions on a substrate, respectively; and

providing a layer between the regions, the layer comprising carbon and a metal.

10. The method of Claim 9, wherein the metal is Pd.

11. The method of Claim 9, wherein the layer comprises primarily carbon.

12. ✓ A method of fabricating an electron-emitting device, comprising the steps of:

disposing a pair of electrodes in first and second regions on a substrate, respectively; and

providing a layer between the regions, the layer comprising an insulating material and at least some conductive particles which protrude from a surface of the layer.

13. The method of Claim 12, wherein the conductive particles comprise a material selected from the group consisting of a metal, a semi-metal, and a semiconductor.

14. The method of Claim 13, wherein the semiconductor is SnO₂.

15. The method of Claim 12, 13, or 14, wherein the insulating material is SiO₂.

16. A method of fabricating an electron-emitting device, comprising the steps of:

disposing a pair of electrodes in first and second regions on a substrate, respectively; and

providing a layer between the regions, the layer comprising carbon and at least some conductive particles.

17. The method of Claim 16, wherein the layer comprises primarily carbon.

18. The method of Claim 17, wherein the conductive particles comprise a material selected from the group consisting of a metal, a semi-metal, and a semiconductor.

19. The method of Claim 13, wherein the metal is Pd.

20. The method of any one of Claims 16-19, wherein at least some of the conductive particles protrude from a surface of the layer.

21. The method of any one of Claims 12-14 and 16-19,
wherein the conductive particles are spatially separated from one
another.

22. The method of any one of Claims 12-14 and 16-19,
wherein diameters of the conductive particles are in a range of
several tens of angstroms to several micrometers.

23. ✓ A method of fabricating an electron-emitting
device, comprising the steps of:

forming an insulating layer on a first portion of
a surface of a substrate, so as to define a step-like structure;

disposing a first electrode on a second portion of
the surface of the substrate;

disposing a second electrode on an upper surface
of the insulating layer; and

providing a layer along a side of the insulating
layer, between the first and second electrodes, the layer
comprising a metal and a semiconductor.

24. The method of Claim 23, wherein the side of the
insulating layer includes a surface which is substantially

perpendicular to the surface of the substrate, and the layer is provided on that surface.

25. The method of Claim 23 or 24, wherein part of the insulating layer also is formed on a portion of the first electrode.

26. The method of Claim 23 or 24, wherein the metal is Pd.

27. The method of Claim 26, wherein the semiconductor is carbon.

28. A method of fabricating an electron-emitting device, comprising the steps of:

forming an insulating layer on a first portion of a surface of a substrate, so as to define a step-like structure;

disposing a first electrode on a second portion of the surface of the substrate;

disposing a second electrode on an upper surface of the insulating layer; and

providing a layer along a side of the insulating layer, between the first and second electrodes, the layer comprising an insulating material and a conductive material.

29. The method of Claim 28, wherein the side of the insulating layer includes a surface which substantially perpendicular to the surface of the substrate, and the layer is provided on that surface.

30. The method of Claim 28 or 29, wherein part of the insulating layer also is formed on a portion of the first electrode.

31. The method of Claim 28 or 29, wherein the conductive material is selected from the group consisting of Pd and SnO₂.

32. The method of Claim 31, wherein the insulating material is SiO₂.

33. A method of fabricating an electron-emitting device, comprising the steps of:

forming an insulating layer on a first portion of
a surface of a substrate, so as to define a step-like structure;
disposing a first electrode on a second portion of
the surface of the substrate;
disposing a second electrode on an upper surface
of the insulating layer; and
providing a layer along a side of the insulating
layer, between the first and second electrodes, the layer
including carbon and at least some conductive particles.

34. The method of Claim 33, wherein the layer
comprises primarily carbon.

35. The method of Claim 33 or 34, wherein the
conductive particles include Pd.

✓ 36. A method of fabricating an electron source that
includes a plurality of electron-emitting devices, each electron-
emitting device comprising a pair of electrodes and a layer
disposed between the electrodes, wherein each electron-emitting
device is prepared by a method comprising the steps of:

disposing the pair of electrodes in first and second regions on a substrate, respectively; and

providing the layer between the regions, the layer comprising a metal and a semiconductor.

✓ 37. A method of fabricating an electron source that includes a plurality of electron-emitting devices, each electron-emitting device being prepared by a method comprising the steps of:

disposing a pair of electrodes in first and second regions on a substrate, respectively; and

providing a layer between the regions, the layer comprising carbon and a metal.

✓ 38. A method of fabricating an electron source that includes a plurality of electron-emitting devices, each electron-emitting device being prepared by a method comprising the steps of:

disposing a pair of electrodes in first and second regions on a substrate, respectively; and

providing a layer between the regions, the layer including an insulating material and at least some conductive

particles, wherein at least some of the conductive particles protrude from a surface of the layer.

✓39. A method of fabricating an electron source that includes a plurality of electron-emitting devices, each electron-emitting device being prepared by a method comprising the steps of:

forming an insulating layer on a first portion of a surface of a substrate, so as to define a step-like structure;

disposing a first electrode on a second portion of the surface of the substrate;

disposing a second electrode on an upper surface of the insulating layer; and

providing a layer along a side of the insulating layer, between the first and second electrodes, the layer comprising a metal and a semiconductor.

✓40. A method of fabricating an electron source that includes a plurality of electron-emitting devices, each electron-emitting device being prepared by a method comprising the steps of:

forming an insulating layer on a first portion of
a surface of a substrate, so as to define a step-like structure;
disposing a first electrode on a second portion of
the surface of the substrate;
disposing a second electrode on an upper surface
of the insulating layer; and
providing a layer along a side of the insulating
layer, between the first and second electrodes, the layer
comprising an insulating material and a conductive material.

✓ 41. A method of fabricating an electron source that
includes a plurality of electron-emitting devices, each electron-
emitting device being prepared by a method comprising the steps
of:

forming an insulating layer on a first portion of
a surface of a substrate, so as to define a step-like structure;
disposing a first electrode on a second portion of
the surface of the substrate;
disposing a second electrode on an upper surface
of the insulating layer; and

providing a layer along a side of the insulating layer, between the first and second electrodes, the layer including carbon and at least some conductive particles.

✓ 42. A method of fabricating an image forming apparatus which includes an electron source and a phosphor plate, the electron source including plurality of electron-emitting devices that are each prepared by a method according to any one of Claims 36-41.

✓ 43. A method of fabricating an electron-emitting device which comprises a pair of electrodes and a layer disposed between the electrodes, the method comprising the steps of:
disposing a pair of electrodes in first and second regions on a substrate, respectively; and
providing the layer between the regions, the layer being a semiconductor layer that includes a metal.

44. The method of Claim 43, wherein the metal is Pd.

45. The method of Claim 43 or 44, wherein the semiconductor layer includes a semiconductor selected from the group consisting of carbon and SnO₂.

✓ 46. A method of fabricating an electron-emitting device, comprising the steps of:

disposing a pair of electrodes in first and second regions on a substrate, respectively; and

providing a layer between the regions, the layer being an insulating layer which includes at least some conductive particles, wherein at least some of the conductive particles protrude from a surface of the layer.

47. The method of Claim 46, wherein the conductive particles include a material selected from the group consisting of a metal, a semi-metal, and a semiconductor.

48. The method of Claim 47, wherein the semiconductor is SnO₂.

✓ 49. A method of fabricating an electron-emitting device, comprising the steps of:

forming an insulating layer on a first portion of a surface of a substrate, so as to define a step-like structure;

disposing a first electrode on a second portion of the surface of the substrate;

disposing a second electrode on an upper surface of the insulating layer; and

providing a layer along a side of the insulating layer, between the first and second electrodes, the layer being a semiconductor layer which includes a metal.

✓ 50. A method of fabricating an electron-emitting device, comprising the steps of:

forming an insulating layer on a first portion of a surface of a substrate, so as to define a step-like structure;

disposing a first electrode on a second portion of the surface of the substrate;

disposing a second electrode on an upper surface of the insulating layer; and

providing a layer along a side of the insulating layer, between the first and second electrodes, the layer being an insulating layer which includes a conductive material.

09587249-060200
✓ 51. A method of fabricating an electron source that includes a plurality of electron-emitting devices, each electron-emitting device being prepared by a method comprising the steps of:

disposing a pair of electrodes in first and second regions on a substrate, respectively; and

providing a layer between the regions, the layer comprising carbon and at least some conductive particles.

✓ 52. A method of fabricating an electron source that includes a plurality of electron-emitting devices, each electron-emitting device comprising a pair of electrodes and a layer disposed between the electrodes, each electron-emitting device being prepared by a method comprising the steps of:

disposing a pair of electrodes in first and second regions on a substrate, respectively; and

providing the layer between the regions, the layer being a semiconductor layer which includes a metal.

✓ 53. A method of fabricating an electron source that includes a plurality of electron-emitting devices, each electron-

emitting device being prepared by a method comprising the steps of:

disposing a pair of electrodes in first and second regions on a substrate, respectively; and

providing a layer between the regions, the layer being a carbon layer which includes a metal.

✓ 54. A method of fabricating an electron source that includes a plurality of electron-emitting devices, each electron-emitting device being prepared by a method comprising the steps of:

disposing a pair of electrodes in first and second regions on a substrate, respectively; and

providing a layer between the regions, the layer being an insulating layer which includes at least some conductive particles, wherein at least some of the conductive particles protrude from a surface of the layer.

✓ 55. A method of fabricating an electron source that includes a plurality of electron-emitting devices, each electron-emitting device being prepared by a method comprising the steps of:

forming an insulating layer on a first portion of a surface of a substrate, so as to define a step-like structure;

disposing a first electrode on a second portion of the surface of the substrate;

disposing a second electrode on an upper surface of the insulating layer; and

providing a layer along a side of the insulating layer, between the first and second electrodes, the layer being a semiconductor layer which includes a metal.

✓ 56. A method of fabricating an electron source that includes a plurality of electron-emitting devices, each electron-emitting device being prepared by a method comprising the steps of:

forming an insulating layer on a first portion of a surface of a substrate, so as to define a step-like structure;

disposing a first electrode on a second portion of the surface of the substrate;

disposing a second electrode on an upper surface of the insulating layer; and

providing a layer along a side of the insulating layer,
between the first and second electrodes, the layer being an
insulating layer which includes a conductive material.

✓ 57. A method of fabricating an image forming apparatus
which includes an electron source and a phosphor plate, the
electron source including a plurality of electron-emitting
devices that are each prepared by a method according to any one
of Claims 51-56.

PATENT APPLICATION

IN THE UNITED STATES PATENT AND TRADEMARK OFFICE

In re Reissue Application:)
of U.S. Patent No.5,759,080 : Examiner: Unassigned
SEISHIRO YOSHIOKA ET AL. :
Appln No.: 09/587,249 : Group Art Unit: 1722
Filed: June 2, 2000 :
For: DISPLAY DEVICE WITH :
ELECTRON-EMITTING DEVICE)
WITH ELECTRON-EMITTING :
REGION INSULATED FROM)
ELECTRODES :

Assistant Commissioner for Patents
Washington, D.C. 20231

REISSUE DECLARATION AND POWER OF ATTORNEY

Sir:

As a below named inventor, I hereby declare and say
that:

1. I believe that I am one of the original, first
and joint inventors of the subject matter which is claimed in
the subject reissue application and for which a reissue
patent is sought on the invention entitled DISPLAY DEVICE
WITH ELECTRON-EMITTING DEVICE WITH ELECTRON-EMITTING REGION
INSULATED FROM ELECTRODES, the specification of which was
filed in the Patent and Trademark Office on June 2, 2000.

002099-6448560

2. I have reviewed and understand the contents of the reissue application, including the claims.

3. I acknowledge my duty to disclose to the U.S. Patent and Trademark Office all information known to be material to patentability as defined in 37 C.F.R. § 1.56.

4. I hereby claim foreign priority benefits under Title 35, United States Code, § 119(a)-(d) or §365(b), of the foreign applications for patent listed below and have also identified below any foreign application for patent or inventor's certificate or PCT international application having a filing date before that of the application on which priority is claimed:

<u>Country</u>	<u>Application No.</u>	<u>Filing Date</u>	<u>Priority Claimed</u>
Japan	62-174837	July 15, 1987	Yes
Japan	62-250448	October 2, 1987	Yes
Japan	62-255063	October 9, 1987	Yes
Japan	62-255068	October 9, 1987	Yes
Japan	63-102485	April 27, 1988	Yes
Japan	63-102486	April 27, 1988	Yes
Japan	63-102487	April 27, 1988	Yes
Japan	63-102488	April 27, 1988	Yes
Japan	63-154516	June 21, 1988	Yes

5. I believe that the original above-identified U.S. Patent is partly inoperative by reason of my having claimed less than I had the right to claim; specifically, new

002090 64248560

Claims 6-57 should be included in the patent. During the prosecution of U.S. Patent Application No. 08/479,000, which matured into the above-identified U.S. Patent, and during the prosecution of U.S. Patent Applications Nos. 08/396,066, 08/191,065, 07/705,720, and 07/218,203, which are parents of U.S. Patent Application No. 08/479,000, the inventors did not appreciate that Claims 6-57 could have been presented for examination. After that patent issued, it was noticed by an official of the Intellectual Property Department of Canon Kabushiki Kaisha, the assignee of the entire interest in the patent, that the invention as defined in those claims could and should have been claimed by the inventors. It was also noticed that minor errors appeared in the application, and that those errors could and should have been corrected as shown by the underlines and brackets in the present reissue application. All errors which are being corrected in the present reissue application up to the time of filing this declaration arose without any deceptive intent on my part.

6. I hereby appoint the practitioners associated with the firm and Customer Number provided below to prosecute this application and to transact all business in the Patent and Trademark Office connected therewith and direct that all

correspondence be addressed to the address associated with
that Customer Number:

FITZPATRICK, CELLA, HARPER & SCINTO

Customer Number: 05514.

I hereby declare that all statements made herein of
my own knowledge are true and that all statements made on
information and belief are believed to be true; and further
that these statements were made with the knowledge that
willful false statements and the like so made are punishable
by fine or imprisonment, or both, under Section 1001 of Title
18 of the United States Code and that such willful false
statements may jeopardize the validity of the application or
any patent issued thereon.

Full Name of Sole or First Inventor SEISHIRO YOSHIOKA
Inventor's signature Seishiro Yoshioka
Date July 31, 2000 Citizen/Subject of JAPAN
Residence 2-5, Fujimino 1-chome, Hiratsuka-shi
Kanagawa-ken, Japan
Post Office Address c/o Canon Kabushiki Kaisha,
30-2, Shimomaruko 3-chome, Ohta-ku, Tokyo, Japan

Full Name of Second Joint Inventor, if any ICHIRO NOMURA
Second Inventor's signature Ichiro Nomura
Date Aug. 3, 2000 Citizen/Subject of JAPAN
Residence 2-1-4-302, Morinosato, Atsugi-shi
Kanagawa-ken, Japan
Post Office Address c/o Canon Kabushiki Kaisha
30-2, Shimomaruko 3-chome, Ohta-ku, Tokyo, Japan

Full Name of Third Joint Inventor, if any HIDETOSHI SUZUKI
Third Inventor's signature Hidetoshi Suzuki
Date Aug. 3, 2000 Citizen/Subject of JAPAN
Residence 927-1-201, Ishikawa, Fujisawa-shi
Kanagawa-ken, Japan
Post Office Address c/o Canon Kabushiki Kaisha
30-2, Shimomaruko 3-chome, Ohta-ku, Tokyo, Japan

Full Name of Fourth Joint Inventor, if any TOSHIHIKO TAKEDA
Fourth Inventor's signature Toshihiko Takeda
Date August. 3, 2000 Citizen/Subject of JAPAN
Residence 3-12-2-205, Morinosato, Atsugi-shi
Kanagawa-ken, Japan
Post Office Address c/o Canon Kabushiki Kaisha
30-2, Shimomaruko 3-chome, Ohta-ku, Tokyo, Japan

Full Name of Fifth Joint Inventor, if any TETSUYA KANEKO
Fifth Inventor's signature Tetsuya Kaneko
Date August. 3, 2000 Citizen/Subject of JAPAN
Residence 4-128, Shimonoya-cho, Tsurumi-ku
Yokohama-shi, Kanagawa-ken, Japan
Post Office Address c/o Canon Kabushiki Kaisha
30-2, Shimomaruko 3-chome, Ohta-ku, Tokyo, Japan

Full Name of Sixth Joint Inventor, if any YOSHIKAZU BANNO

Sixth Inventor's signature Yoshikazu Banno

Date August 2, 2000 Citizen/Subject of JAPAN

Residence 7-23-6-208, Tamagawagakuen, Machida-shi

Tokyo, Japan

Post Office Address c/o Canon Kabushiki Kaisha

30-2, Shimomaruko 3-chome, Ohta-ku, Tokyo, Japan

Full Name of Seventh Joint Inventor, if any KOJIRO YOKONO

Seventh Inventor's signature Kojiro Yokono

Date August 2, 2000 Citizen/Subject of JAPAN

Residence 2-14-308, Namiki 2-chome, Kanazawa-ku

Yokohama-shi, Kanagawa-ken, Japan

Post Office Address c/o Canon Kabushiki Kaisha
